

Leading the Way...

Why the Danné AntiAgeing is New Zealand's leading Pre and Post Care System for Cosmetic Surgeons.

Dr Greg Taylor recently set up his own in-house pre and post care clinic utilising the Danné System of skin care with its unique philosophy. Dr Taylor's surgery offers the full range of plastic cosmetic and laser surgical procedures, prepared and maintained by Danné Enzyme treatments and supportive Danné home care that is prescribed to patients.

The full team includes Anne Nicholas, Practice Manager, Geraldine Braid, Theatre Nurse and Jeanine Chell, Danné Therapist who all contribute to creating the best possible result for the patient.

Dr Taylor says "we want to provide the very best service in New Zealand and be able to eliminate all signs of cosmetic surgery and minimise down time for the client by using the most powerful pre and post care treatment system through the Danné philosophy. I am confident that we have a system that not only works with our surgical needs, but enhances the results to form part of an AntiAgeing programme that is unrivalled in cosmetic surgery in NZ."

Jeanine Chell, a specialised Danné therapist, recently began Danné post care on a 'face lift' patient. This involves a detailed consultation after the surgical procedure and the application of a Beta Glucan based serum followed by an antiseptic and epidermal growth factor crème called ContraDerm. Specialised Enzyme treatments are used right up to the sutures to stimulate the skin right through to the dermis layer. This is called Danné transdermal delivery and was one of the core features of a system started some 40 years ago by global educator Dr Danné Montague-King, based on achieving critical results.

Jeanine commented "Because the Enzyme treatments are so powerful, they activate the immune system in the skin to turbo charge it and this can actually be seen in the 'plasmatic effect', thereby preparing the skin for the special marine and botanical home care applications." Danné home care has been designed to supply the maximum biological ingredients that will feed the skin in times of need and maintain it at its optimum level.

At a microbiological level, post surgery, the Danné System works by rebuilding cells and reducing inflammation. Danné Enzyme treatments deliver dermal amino acids deep into the skin and create the rebuild process through accelerated oxygenation, increased metabolic rate, nutrient supply, toxin extraction and reverse osmosis exfoliation. The formation of collagen is dependant on the fibroblasts and Vitamin C to fuse key triplet amino acids lysine, glycine and proline, which are all delivered transdermally in our core base AntiAgeing Enzyme treatment.

The Danné system initially uses Beta Glucan to stimulate the macrophages, which help to reduce the inflammation phase of post surgery. The re-epithelization phase which includes stimulation of keratinocytes, tonofibrilles, tonofilaments, keratinosomes and demosomes, to name a few, are activated

through dermal enzyme treatments which trigger cell differentiation followed by the keratinization process. Each Danné home care prescriptive is designed for a specific purpose to take care of a specific dermal process, yet all work together to create a synergistic result.

The third phase of rebuild known as 'Granulation Tissue Formation' occurs through the formation of new collagen, glycoproteins and glycosaminoglycans, which we also stimulate with amino acids from Enzyme treatments and additionally through Vitamin C and A infusion. The Danné system has been known for years for its use of Vitamin C and

A to provide effective results in 30 countries, used by advanced therapists and plastic surgeons.

The Danné system uses Herb and Mineral Mist and SebaE to rebuild the essential dermal lipid barriers in the upper epidermis to prevent dehydration and deterioration which results in fine lines, poor tone, texture and accelerated ageing. At Danné we believe the application of these two complex Danné dermal replicating formulations help to support and regulate the enzyme transglutaminase, which manages the ceramides in the lipid bi-layers of the epidermis. Through the results we achieve at Danné New Zealand as an educator, distributor and research agent, it is part of our philosophy to continue researching how our special system works with the chemistry of skin and beauty for the benefit of all clients and patients.

Matt Clark, Manager for Danné New Zealand says "With post surgical rebuilding the skin performs an extremely complex process in conjunction with the immune system, but if we can match the microbiology of the skin with biochemistry of nature, results are automatic and this is what the Danné system achieves time after time."

One of the most important features of reducing all visible signs of cosmetic surgery is the use of a non-reactive SPF30 Sunblock, which is applied when sutures are removed and there is exposure to the normal environment and UV rays. This will prevent any destruction of the melanocytes, which can turn surgical incisions into white scars.
